FOR AUTHORS

- 1. The monthly "Wiadomości Lekarskie" Journal is the official journal of the Polish Medical Association. Original studies, review papers as well as case reports are published.
- 2. In 2022, the cost of publishing the manuscript is PLN 1,500 plus 23% VAT. From 2022, the publication costs for foreign authors amount to EUR 450, of which EUR 50 is payable with the submission of the article (includes the costs of review, anti-plagiarism system, English language level assessment, checking the compliance of the manuscript with the regulations of the publishing house, etc.), and the remaining EUR 400 after accepting the article for publication. Thanks to obtaining funding for authors from Ukraine, the cost of publication for Ukrainian authors is EUR 350. EUR 50 is payable together with the submission of the article, and EUR 300 after accepting the article for publication. The publisher issues invoices. If the first author of the manuscript is a member of the Editorial Board, we do not charge a fee for printing the manuscript. Membership of the Polish Medical Association with documented paid membership fees for the last 3 years is also the exempt from publication fee.
- Only papers in English are accepted for publication. The editors can help in finding the right person for translation or proofreading.
- 4. Papers should be sent to the editor via the editorial panel (Editorial System), available on the journal's website at https://www.wiadlek.pl. In order to submit an article, free registration in the system is necessary. After registration, the author should follow the instructions on the computer screen.
- 5. All editorial work is under control and using the editorial panel. This applies in particular to sending manuscripts, correspondence between the editor and author and the review process. In special cases, the editor may agree to contact outside the panel, especially in case of technical problems.
- 6. Acceptable formats for individual elements of the article are as follows:
- A) Content of the article doc, docx, rtf, odt.
- B) Tables doc, docx, rtf, odt
- C) Figures JPG, GIF, TIF, PNG with a resolution of at least 300 dpi
- D) Captions for figures and tables
- These elements are sent to the editor separately using the editorial panel. References and article metadata such as titles, keywords, abstracts etc. are supplemented by the author manually in the editorial panel in appropriate places.
- 7. The volume of original papers including figures and references must not exceed 21,600 characters (12 pages of typescript), and review papers up to 28,800 characters (16 pages).
- The original manuscript should have the following structure: Introduction, Aims, Material and methods, Results, Discussion and Conclusions which cannot be a summary of the manuscript.
- 9. When using abbreviations, it is necessary to provide the full wording at the first time they are used.
- 10. In experimental manuscripts in which studies on humans or animals have been carried out, as well as in clinical studies, information about obtaining the consent of the Ethics Committee should be included.
- 11. The Editorial Board follow the principles contained in the Helsinki Declaration as well as in the Interdisciplinary Principles and Guidelines for the Use of Animals in Research, Testing and Education, published by the New York Academy of Sciences Ad Hoc Committee on Animal Research. All papers relating to animals or humans must comply with ethical principles set out by the Ethics Committee.
- 12. The abstract should contain 150-250 words. Abstracts of original, both clinical and experimental, papers should have the following structure: Aims, Material and methods, Results, Conclusions. Do not use abbreviations in the title or the abstract. The abstract is pasted or rewritten by the authors into the appropriate field in the application form in the editorial panel.
- Keywords (3-5) should be given according to MeSH (Medical Subject Headings Index Medicus catalogs – http://www.nim.nih.gov.mesh/MBrower.html). Keywords cannot be a repetition of the title of the manuscript.
- 14. Illustrative material may be black and white or color photographs, clearly contrasting or drawings carefully made on a white background. With the exception of selected issues, the Journal is printed in shades of gray (black and white illustrations).
- 15. The content of the figures, if present (e.g. on the charts), should also be in English
- 16. Links to all tables and figures (round brackets) as well as references (square brackets) the author must place in the text of the article.

- 17. Only references to which the author refers in the text should be included in the list of references ordered by citation. There should be no more than 30 items in original papers and no more than 40 items in review papers. Each item should contain: last names of all authors, first letters of first names, the title of the manuscript, the abbreviation of the journal title (according to Index Medicus), year, number, start and end page. For book items, please provide: author's (authors') last name, first letter of the first name, chapter title, book title, publisher, place and year of publication. It is allowed to cite websites with the URL and date of use of the article, and if possible the last names of the authors. Each literature item should have a reference in the text of the manuscript placed in square brackets, e.g. [1], [3-6]. Items should be organized as presented in Annex 1 to these Regulations.
- 18. When submitting the article to the editor, the authors encloses a statement that the work was not published or submitted for publication in another journal and that they take full responsibility for its content, and the information that may indicate a conflict of interest, such as:
 - 1. financial dependencies (employment, paid expertise, consulting, ownership of shares, fees),
 - 2. personal dependencies,
 - 3. academic and other competition that may affect the substantive side of the work,
- sponsorship of all or part of the research at the stage of design, collection, analysis and interpretation of data, or report writing.
- 19. The authors in the editorial panel define their contribution to the formation of scientific work according to the following key:
 - A Work concept and design
 - B Data collection and analysis
 - C Responsibility for statistical analysis
 - D Writing the article
 - E Critical review
 - F Final approval of the article.
- In the editorial panel along with the affiliation, the author also gives her or his ORCID number.
- 21. The Journal is reviewed in double, blind review mode. The submitted papers are evaluated by two independent reviewers and then qualified for publishing by the Editor-in-Chief. Reviews are anonymous. The authors receive critical reviews with a request to correct the manuscript or with a decision not to qualify it for publishing. The procedure for reviewing articles is in line with the recommendations of the Ministry of Science and Higher Education contained in the paper "Good practices in review procedures in science" (Warsaw 2011). Detailed rules for dealing with improper publishing practices are in line with COPE guidelines. The publishing review rules are in the Review Rules section.
- 22. Each manuscript is subject to verification in the anti-plagiarism system.
- 23. Manuscripts are sent for the author's approval. The author's corrections should be sent within the time limit indicated in the system. No response within the given deadline is tantamount to the author's acceptance of the submitted material. In special cases, it is possible to set dates individually.
- 24. Acceptance of the manuscript for publishing means the transfer of copyright to the Aluna Publishing House (Aluna Anna Łuczyńska, NIP 5251624918).
- 25. Articles published on-line and available in open access are published under Creative Common Attribution-Non Commercial-No Derivatives 4.0 International (CC BY-NC-ND 4.0) allowing to download articles and share them with others as long as they credit the authors and the publisher, but without permission to change them in any way or use them commercially.
- 26. The authors receive a free PDF of the issue in which their mansucript is enclosed, and on request a printed copy. The printed copy is sent to the address indicated by the authors as the correspondence address.
- 27. Manuscripts not concordant with the above instructions will be returned to be corrected.
- 28. The editors do not return papers which have not been commissioned.
- 29. The editors take no responsibility for the contents of the advertisements.

ABSTRACT

The aim: To investigate the status and possibilities of markers of the inflammatory response of organism in infants with identified IUI born to mothers diagnosed with TORCH infection. **Materials and methods:** The study group included: infants diagnosed with IUI (n = 40), born to mothers (age 31.31 ± 2.08 years) with the diagnosis of TORCH infection and a control group (n = 25 infants). Childbirth in all newborns was physiological. The average weight of newborns was 1877.69 \pm 981.78 g (min – 600 g; max – 4000 g). Gestational age: 32.25 ± 5.15 weeks. Observation and treatment of newborns lasted up to 7 days (included stay in the emergency department of the Uzhhorod maternity hospital in the Zakarpattia region). Cytokine profile, γ -IFN, TNF- α , Pg E2, serum neopterin and procalcitonin levels were studied.

Results: The values of the parameters of the cytokine profile (IL-1, IL-6, IL-8, IL-10) varied within the reference values, but with significant differences with the values of the control group, which was 1,2; 4; 10; 6 times, respectively. The levels of inflammatory mediators (γ -IFN Procalcitonin Neopterin TNF- α Pg E2) differed significantly from the data of the control group of infants and exceeded the upper limit of the reference values by 1,3; 3; 25; 4 times, respectively. According to the correlation analysis, there are positive correlations of medium level: IL 1 and procalcitonin (r = 0.33); IL 6 and IL10 (r = 0.44); IL 10 and prostaglandin E2 (r = 0.44); neopterin and prostaglandin E2 (r = 0.39), which indicates synergism in the performance of biologically active processes. Negative correlations of moderate degree were observed between the following parameters: IL 1 and gestational age of infants (r = -0.36); IL 6 and IL 8 (r = -0.34); γ -IFN and TNF- α (r = -0.43), which indicates the diversity of interactions between participants in the inflammatory response of the organism.

Conclusions: Various infectious agents can act as «primary affect» of sepsis as a complex pathological process involving the organism, and each of the infections has its own characteristics of the pathological process, therefore current changes in infectious circumstances make new demands on research. It has been proven that intrauterine infection has a negative effect on the homeostatic parameters of infants, in particular, on the indicators of the inflammatory response of the child's organism. Symptomatic inflammatory biomarkers can be used to identify the pathological condition of the infant, in addition to routine laboratory tests, for early correction of VUI. This delay in identifying affected infants can lead to long and unnecessary therapy, the emergence of resistant strains of microorganisms, increased treatment costs and, in particular, a higher risk of complications such as cerebral palsy or intraventricular hemorrhage.

KEY WORDS: intrauterine infection, inflammatory response, cytokine profile, newborns

Wiad Lek. 2022;75(4 p2):974-981

INTRODUCTION

One of the biggest problems that doctors face is deciding when to diagnose an intrauterine infection and what correction to prescribe. Intrauterine infections (IUI) and neonatal sepsis are the most relevant and controversial issues of modern neonatology, given that infectious pathology determines a high level of morbidity and mortality in newborns [1, 2]. In recent years, the problem of IUI has become particularly relevant, as the achievements of modern resuscitation allow to ensure the survival of newborns who have suffered severe IUI [3, 4]. The results of studies conducted in obstetrics and gynecology and neonatal clinics have shown that a variety of opportunistic pathogens not only cause acute and chronic inflammatory processes of the pelvis of the pregnant woman, but also lead to severe of the IUI fetus and newborn, and can form pathology directly not associated with the

development of the inflammatory process [5, 6]. IUI is an established fact of intrauterine penetration of microorganisms into the fetus, in which there are pathophysiological changes characteristic of infectious pathology, manifested prenatally or shortly after birth, while intrauterine infection of the fetus and newborn is the pathological condition formed under the influence of infectious pathology of the mother. associated infection of amniotic fluid, placenta, umbilical cord, fetus on the background of changes in the immunological reactivity of the newborn without signs of infectious disease [7, 6]. The frequency of IUI has not been definitively established, however, according to resources, the prevalence of IUI can reach 10-15% of all pregnancies, and intrauterine infection ranges from 6 to 55%, reaching 80% among premature infants. In the structure of IUI viral and / or virus-associated infections are the most dangerous

Laboratory indicators	M ± m (n=40)	min	max	Reference values	Control group (n=25)
IL-1, pg/ml	0,83 ± 0,73•	0,00	3.39	0-11pg/ml 1,6 pg/ml	0,65 ± 0,06

and difficult to predict. Viral infections during pregnancy lead to a number of consequences for the mother and fetus, ranging from asymptomatic disease to critical conditions that cause severe maternal morbidity, stillbirth, premature birth, birth defects and congenital anomalies that become apparent at birth or later [5, 8]. The highest risk of infection of the fetus is observed in the case of primary infection of the pregnant woman [9]. Thus, IUI, especially viral, remain almost uncontrollable causes of reproductive loss, childhood morbidity and disability. Pathological effects of microorganisms on the fetus during pregnancy lead to various disorders, including abortion, organ defects, the development of severe infectious inflammation or latent process with elements of persistence in the postnatal period. IUI infection is often accompanied by the development of life-threatening conditions in newborns, which determining the medical and social significance of the problem and requires further in-depth research.

THE AIM

To investigate the status and possibilities of markers of the inflammatory response of organism in infants with identified IUI born to mothers diagnosed with TORCH infection.

MATERIALS AND METHODS

The study group included: infants diagnosed with IUI (n = 40), born to mothers (age 31.31 ± 2.08 years) with the

diagnosis of TORCH infection and a control group (n = 25 infants). Childbirth in all newborns was physiological. The average weight of newborns was 1877.69 \pm 981.78 g (min – 600 g; max – 4000 g). Gestational age: 32.25 \pm 5.15 weeks. Observation and treatment of newborns lasted up to 7 days (included stay in the emergency department of the Uzhhorod maternity hospital in the Zakarpattia region). Cytokine profile, γ -IFN, TNF- α , Pg E2, serum neopterin and procalcitonin levels were studied.

RESULTS

The examination revealed pathological changes in the levels of immunological parameters and inflammatory response factors of the organism, their interactions and relationships (table I.).

According to table I, there is a significant increase in the level of IL-1 ($0.83 \pm 0.73 \text{ pg} / \text{ml}$) compared to the control group ($0.65 \pm 0.06 \text{ pg} / \text{ml}$), but within the reference values; significant increase in IL-6 levels by 14-fold ($10.79 \pm 5.24 \text{ pg} / \text{ml}$) compared to controls group of infants ($0.77 \pm 0.04 \text{ pg} / \text{ml}$) and within the upper limit of reference. The level of IL-8 in the studied contingent ($4.56 \pm 3.72 \text{ pg} / \text{ml}$) also differs significantly from the data of the control group ($0.48 \pm 0.056 \text{ pg} / \text{ml}$), almost 10 times, but the variation occurs within the reference. There is also a significant, difference between the values of IL-10 ($7.78 \pm 6.65 \text{ pg} / \text{ml}$) from the values of the control group ($1.2 \pm 0.25 \text{ pg} / \text{ml}$).

Consequently, the values of the cytokine profile varied within the reference values, but with significant differences

Laboratory indicators	Pearson's correlation coefficient, r	Statistical signifacance, p
IL-1 Procalcitonin	0,33	0,04
IL-1 Gestational age	0,36	0,02
IL-6 IL-8	0,34	0,03
IL-6 IL-10	0,44	0,005
γ-IFN TNF-α	-0,43	0,006
Pg E IL-10	0,44	0,006
Pg E2 Neopterin	0,39	0,02

Table II. Statistically significant correlations between the studied laboratory parameters

with the values of the control group, which was 1,2;14;10; 6 times, respectively.

The level of γ -IFN (20.14 ± 25.56 pg / ml) also differed significantly (in 4 times) from the data of the control group $(5.8 \pm 0.3 \text{ pg} / \text{ml})$ and exceeded the reference values by 1.3 times. The value of procalcitonin $(1.67 \pm 1.09 \text{ ng}/\text{ml})$ differed significantly from the control group $(7.6 \pm 1.5 \text{ ng} / \text{ml})$ and exceeded the upper limit of reference by 3 times. The level of Neopterin $(32.32 \pm 18.50 \text{ nmol} / \text{l})$ differed significantly (267 times) from the data of the control group $(0.12 \pm 0.022 \text{ nmol})$ / l) and was 3 times higher than the upper limit of the reference. The value of TNF- α (157.21 ± 21.05 pg/ml) in the study group differed significantly from the data of the control group $(8.4 \pm 0.32 \text{ pg} / \text{ml})$ and was 25 times higher than the upper limit of reference. The Pg E2 study also presented a significant difference in levels $(1671.38 \pm 1555.16 \text{ pg} / \text{ml compared to})$ $390.21 \pm 31.19 \text{ pg} / \text{ml}$), which was a significant difference in data and exceeded the upper limit of reference by 4 times.

Therefore, the values of γ -IFN Procalcitonin Neopterin TNF- α Pg E2 differed significantly from the data of the control group of infants and exceeded the upper limit of the reference values by 1,3; 3; 25; 4 times, respectively.

A correlation analysis of the relationships between the studied parameters was performed, and reliable correlation coefficients of different degrees were identified (Table II.).

According to table II, there is a correlation between the average level of IL-6-IL-10 (r = 0.44) and IL-6 -IL-8 (r = -0.34), which corresponds to the physiological patterns of interactions between interleukins. IL-1, 6 – make up the group of pro-inflammatory interleukins, while IL-10 belongs to the anti-inflammatory group. IL-10 suppresses the production of almost all proinflammatory cytokines and prevents the adhesion of leukocytes to the endothelium, inhibits the secretion of superoxide radicals and cytokines (IL6, IL8, TNF α) [8]. According to leading scientists, IL-10 has been shown to inhibit the effect of interferon- γ and neopterin synthesis by monocytes / macrophages.

A complete immune response is provided only by active interaction between cytokines. The biological effect of one

cytokine is usually realized together with the action of others. The main correlograms of relationships between the participants in the inflammatory response are as follows.

Consider the correlogram of the relationship between the level of γ -IFN and TNF- α in the blood of examined newborns (Fig. 1.)

It is known that cytokines have a wide range of biological properties – interact with each other, form a universal network that triggers and regulates the cascade of inflammatory, immune, metabolic processes – both local and systemic, aimed at neutralizing and eliminating pathogens. In addition to cytokines, interferons also belong to inflammatory mediators involved in the development of the inflammatory response. The main proinflammatory mediators are TNF- α and IL-1. The role of TNF- α in the development of sepsis is associated with: increasing the procoagulant properties of the endothelium, activation of neutrophil adhesion, induction of other proinflammatory cytokines, stimulation of catabolism, fever, synthesis of acute phase proteins.

The importance of IFN γ in the immune system is ascribed to its ability to directly inhibit viral replication, as well as its ability to act as immunostimulator and immunomodulator. According to our data, the multidirectional correlation between the levels of γ -IFN and TNF- α in the blood of the examined newborns is r = -0.43, which is due to the characterological data of the considered indicators.

Consider the correlogram of the relationship between the levels of IL-6 and IL-10 in the blood of examined newborns (Fig. 2.)

Interleukins are cytokines responsible for the transfer of information between leukocytes. When used, one group of leukocytes may affect another. Interleukin 6 (IL 6) is multidirectional. It is produced by monocytes and macrophages. IL 6 directly and effectively stimulates inflammatory processes. However, high concentrations of this substance can limit the development of inflammation. This is because interleukin 6 blocks the synthesis of inflammatory cytokines through a feedback inhibition mechanism. IL-6 is a proinflammatory

Fig. 1. Correlation between γ -IFN and TNF- α levels in the blood of examined newborns.

cytokine with two directions of action. On the one hand, it inhibits the production of proinflammatory cytokines by macrophages, on the other hand, it induces the production of acute phase proteins, promotes the activation of T lymphocytes by antigen-presenting cells, enhances B cell proliferation and induces the formation of immunoglobulins, stimulates hematopoiesis and platelet formation, is synthesized by activated macrophages and T cells [10,11]. Increase in the level of the anti-inflammatory cytokine IL10 can be explained by increase in secretion in response to the elevated content of pro-inflammatory cytokines in the serum. IL10 suppresses the production of almost all proinflammatory cytokines, inhibits leukocyte adhesion to the endothelium and inhibits the secretion of superoxide radicals and cytokines (IL6, IL8, TNFa). The positive correlation coefficient between interleukins 6 and 10 (r = 0.44)demonstrated compliance with the classical rules.

Consider the correlogram of the relationship between Procalcitonin and Interleukin 1 (Fig. 3.)

Fig. 2. Correlation between IL-6 and IL-10 levels in the blood of examined newborns

Interleukin 1 (IL 1) defines a whole group of cytokines that are crucial in the inflammatory process, are the main trigger mechanism for initiating the production of other proinflammatory cytokines. As a result, the biochemical and functional cascade of inflammatory pathobiochemical processes is developing. It is produced in response to a variety of antigens.

The Procalcitonin test also has a high diagnostic potential, which can be traced in our studies and allows to diagnose the disease, determine the severity, course and subsequent prognosis. Synergism of interactions and a positive correlation with the proinflammatory cytokine Interleukin-1 (r = 0.33) is observed.

An important milestone in research is the gestational age of infants, which has significant effects on the development of the disease and the nature of the inflammatory process. Here is a correlogram of relationships (Fig. 4.).

When analyzing the correlogram (Fig. 4) attention should be payed to the features of nonspecific resistance in

the fetus and newborn. Intrauterine capacity of phagocytic cells is relatively insignificant. After birth, the phagocytic ability of leukocytes increases. At the same time, both neutrophils and monocytes in the first 6 months of life do not cope with the final phase of phagocytosis - the destruction of the ligand, which is especially evident in relation to pathogenic microorganisms. At this age, the child's phagocytes are unable to fight pneumococci, which explains the frequent occurrence of pneumonia and relatively high mortality in infants. In the newborn, along with the imperfection of phagocytosis, there is a low ability to synthesize interferons [1,8]. In this regard, the newborn has a tendency to generalized bacterial inflammation and sepsis. These patterns are observed in our studies. The IL-1 relationship and gestational age have a mid-inverse correlation (r = -0.36). This fact can be interpreted as follows: the smaller the gestational age, the greater the production of IL-1 due to physiological age characteristics.

Consider the correlogram of the relationship between the levels of IL-6 and IL-8 in the blood of examined newborns (Fig. 5.)

The action of IL-6 is realized after interaction with two components of a specific heterodimeric receptor (gp130 and IL-6R). IL-6 is a proinflammatory cytokine with two directions of action. On the one hand, it inhibits the production of pro-inflammatory cytokines by macrophages, on the other hand, it induces the production of acute phase proteins (which activate corticosteroid synthesis), promotes the activation of T-lymphocytes by antigen-presenting cells, enhances B-cell proliferation and induces the formation of immunoglobulins, stimulates hematopoiesis and platelet formation. IL-8 is one of the main proinflammatory chemokines formed by macrophages, epithelial and endothelial cells. Interleukin 8 (IL 8) is a cytokine that stimulates the migration of immune cells throughout the body. This means that it stimulates the movement and

Fig. 5. Correlation between IL-6 and IL-8 levels in the blood of examined newborns

Fig. 7. Correlation between IL-10 and Prostaglandin E2 levels in the blood of examined newborns

distribution of T lymphocytes, neutrophils and monocytes. This action is defensive in nature. [8]. According to our data (Fig. 5). , there is a correlation relationship of the middle level (r = 0.44), which presents the unidirectionality of the interaction of biologically active substrates.

Consider the correlogram of the relationship between the levels of Neopterin and Prostaglandin E2 in the blood of examined newborns (Fig. 6.).

In the inflammatory process, an important role belongs to the mediators of inflammation - cytokines. However, the concentration of separate cytokines reflects only a limited view of the interaction between them and immunocompetent cells. Therefore, it is best to measure the level of Neopterin. Neopterin is a substance that is synthesized by monocytes and macrophages under the influence of interferon γ and to a lesser extent by activated vascular endothelial cells. Neopterin plays a role in the mechanism of cytotoxic action of activated macrophages. Its concentration reflects the combined effect of different cytokines on the population of monocytes / macrophages. Prostaglandins have an extremely wide range of physiological effects, are among the most active biological substances, which perform three main functions in the body: supportive, molecular, mediatory. The participation of prostaglandins in the inflammatory process has been proven. They are able to change the activity of enzymes, affect the synthesis of hormones and adjust their action on various organs and tissues. Imbalance in synthesis leads to the development of various diseases[8]. Thus, prostaglandins F2 and E2 are formed in the tissues of the respiratory tract, in particular E is synthesized in the lung tissue in the bronchi and can cause contraction of the bronchial muscles. Prostaglandins can be attributed to intracellular low molecular weight regulators, but they are also active in the extracellular space. Correlation analysis (Fig. 6.).of the obtained results showed positive dependences of the average level of Neopterin concentration on PgE2 (r = 0.39, p = 0.02).

Consider the correlogram of the relationship between the levels of IL-10 and Prostaglandin E2 in the blood of examined newborns (Fig. 7).

According to our data(Fig. 7)., there are significant correlations between the levels of IL-10 and Prostaglandin E2. In inflammation, PgE2 is involved in all processes that lead to the classic signs of inflammation: redness, swelling, pain. It also has immunomodulatory properties and effects on growth, bone structure, which is especially important for infants. IL10 suppresses the production of almost all proinflammatory cytokines, inhibits the adhesion of leukocytes to the endothelium and inhibits the secretion of superoxide radicals and cytokines, inhibits the effect of interferon on the synthesis of neopterin by monocytes / macrophages. The increase in the level of the anti-inflammatory cytokine IL10 can be explained by the increase in the secretion of this cytokine in response to the increased content of pro-inflammatory cytokines in the serum [8,12].

According to the results of correlation analysis, a positive moderate relationship between Pg E2 and IL-10 (r = 0.44, p = 0.006) was presented.

DISCUSSION

Modern research shows that the most common intrauterine infection of the fetus is caused by viral infections of the mother. The range of viruses that cause congenital pathology is constantly expanding. In addition to rubella, HSV, CMVand some others. Pathogens of infectious diseases of the mother during pregnancy are especially dangerous for the fetus, because the fetus lacks both active and passive immunity to microorganisms, which determines the development of the infectious process. Because most of the diseases of pregnant women that leading to IUI occur in subclinical, latent form with activation of the process in any violation of homeostasis, it complicates the clinical diagnosis. Thus, diagnostics based on clinical manifestations only, without involvement of specific microbiological studies, leads to diagnostic errors in 90-95% of cases. It is known that cytokines have a wide range of biological properties - interact with each other, form a universal network that triggers and regulates the cascade of inflammatory, immune-metabolic processes - both local and systemic, aimed at neutralizing and eliminating pathogens. Markers of inflammatory response in newborns diagnosed IUI present changes at all levels, The values of the cytokine profile parameters are within the reference values but have significant differences from the data of the control group according to our data. The levels of other inflammatory mediators (y-IFN Procalcitonin Neopterin TNF-a, Pg E2) exceeded the upper limit of the reference values in 1,3,3, 25, 4 times, respectively, and significantly differed from the data of the infants control group. Immunological immaturity of the newborn can lead to a violation of the response to infectious agents. Various infectious agents can act as «primary affect» of sepsis as a complex pathological process involving the organism, and each of the infections has its own characteristics of the pathological process, therefore curent changes in infectious circumstances make new demands on research. It has been proven that intrauterine infection has a negative effect on the homeostatic parameters of infants[6], in particular, on the indicators of the inflammatory response of the child's organism. Symptomatic inflammatory biomarkers can be used to identify the pathological condition of the infant, in addition to routine laboratory tests, for early correction of VUI. This delay in identifying affected infants can lead to long and unnecessary therapy, the emergence of resistant strains of microorganisms, increased treatment costs and, in particular, a higher risk of complications such as cerebral palsy or intraventricular hemorrhage.

CONCLUSIONS

- 1. The values of the parameters of the cytokine profile (IL-1, IL-6, IL-8, IL-10) varied within the reference values, but with significant differences with the values of the control group, which was 1,2; 4; 10; 6 times, respectively.
- 2. The levels of inflammatory mediators (γ -IFN Procalcitonin Neopterin TNF- α Pg E2) differed significantly from the data of the control group of infants and exceeded the upper limit of the reference values by 1,3; 3; 25; 4 times, respectively.

- 3. According to the correlation analysis, there are positive correlations of medium level: IL 1 and procalcitonin (r = 0.33); IL 6 and IL10 (r = 0.44); IL 10 and prostaglandin E2 (r = 0.44); neopterin and prostaglandin E2 (r = 0.39), which indicates synergism in the performance of biologically active processes.
- 4. Negative correlations of moderate degree were observed between the following parameters: IL 1 and gestational age of infants (r = -0.36); IL 6 and IL 8 (r = -0.34); γ -IFN and TNF- α (r = -0.43), which indicates the diversity of interactions between participants in the inflammatory response of the organism.
